

# Electrical Current

---

# Electrical Current

- \* The amount of charge that passes a point in a conducting wire every second
- \* Represented by  $I$
- \* Measured in amperes (coulomb/second)
- \* Measured using an ammeter

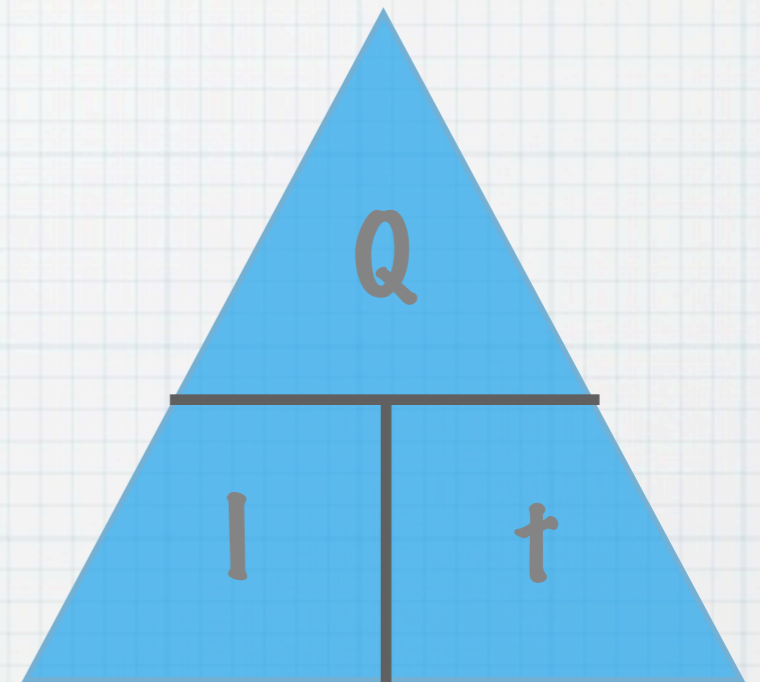

# Electric Current

\*  $I = Q / t$

\* I=current (measured in amperes)

\* Q= charge moving past a point (measured in coulombs)

\* t=time (measured in seconds)

# Sample Calculation

- \* If 240 coulombs of charge pass a point in a wire in five minutes, what is the current through that point in the wire?
- \* Given
  - \*  $Q=240\text{ C}$  (Charge)
  - \*  $t=5\text{ min}$  (time)

# Sample Calculation

- \* First, time must always be in seconds
- \*  $t=5\text{min}$
- \*  $t=5\text{ min} \times 60\text{ seconds} = 300\text{ seconds}$

# Sample Calculation

- \* Required: I (current)
- \*  $I = Q / t$
- \*  $I = 240 \text{ C} / 300 \text{ sec}$
- \*  $= 0.80 \text{ A}$
- \* Therefore 0.80A will move through that point in the conductor.

# Potential Difference

---

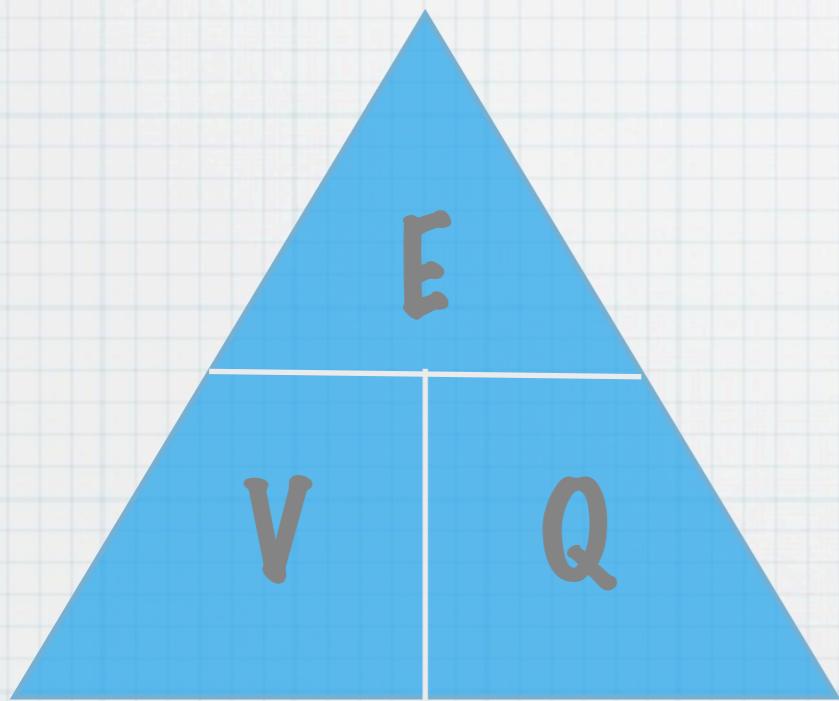

# Potential Difference

- \* **Electrical Potential Energy:** Electrical energy that is stored in a battery
- \* **Joules(J):** Measure of energy
- \* **Potential Difference:** the difference in potential energy per coulomb of charge at one point of the circuit compared to another point.
- \* **Unit:** Volt = J/C (Joule/Coulomb)

# Potential Difference

\*  $E = V \times Q$

\*  $E$  = energy (measured in joules)

\*  $V$  = Volts (measured in joules per coulomb)

\*  $Q$  = charges passing a certain point (coulombs)

# Sample Calculation

- \* In a battery, 45 J of chemical energy are converted into electrical energy  $y$  separating positive and negative charges. The energy places 15 C of charge at the negative terminus, leaving a deficit at the positive terminus. What is the potential difference between the negative and positive terminals of the battery?

# Sample Calculation

\* Given

\*  $E = 45 \text{ J}$

\*  $Q = 150$

\*  $v = ?$

# Sample Calculation

- \* Solution

- \*  $V = E/Q$

- \*  $V = 45 \text{ J} / 15\text{C}$

- \*  $V = 3 \text{ J/C}$

- \* A battery that uses 45 J of chemical energy to separate 15C of charge has a potential difference of 3 J/C.

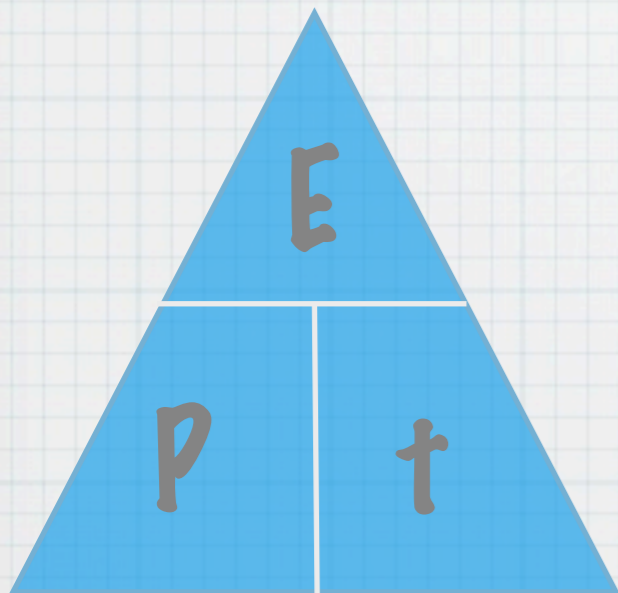

# Electrical Power

---

# Electrical Power

- \* Electrical Power is the amount of energy per unit time

- \* Measured in Watts (J/s)

- \*  $P$  = Power, measured in watts

- \*  $E$  = Energy, measured in joules

- \*  $T$  = Time, measured in seconds

# Calculating Efficiency

---

# Calculating Efficiency

- \* Efficiency is a measure of how much useful energy a device produces compared to the energy supplied to that device
- \* Percent Efficiency =  $\frac{\text{useful energy output}}{\text{total energy input}} \times 100$

# Sample Calculation

\* A light bulb uses 100 J of energy and produces 35 J of light. Calculate the percent efficiency of the light bulb

\* Answer

$$* 35 \text{ J} / 100 \text{ J} \times 100$$

$$* 35\%$$

# Parallel vs Series Circuits

---

A quick review

# Series Circuits

- \* **Series Circuits:**
  - \* **Has one path for current to flow**
  - \* **Current is the same at any point in the circuit**
  - \* **If a bulb is unscrewed, the current stops flowing**

# Parallel Circuits

- \* Parallel Circuits:

- \* More than one pathway for current to flow

- \* Current is not the same at each point in the circuit (Differs at each branch)

- \* If one bulb goes out, the other will not because they still have a supply of electrons

- \*

# Parallel Circuits

## \* Characteristics of Parallel Circuits

- \* 1) If one bulb in one branch burn out, the bulbs in the remaining branched continue flowing.
- \* 2) The current (amps) can vary in each branch. The sum of the current in all branches is equal to that supplied by the battery

# Parallel Circuits

- \* Characteristics of Parallel Circuits
- \* 3) One bulb glows as brightly as two bulbs
